

# Chapter Goals

- Data transformation and cleansing techniques.

# General Lab Guidelines

- Visualization.
  - Modifiable code snippets.
- 

```
# Loading a dataset
# dataset names: "airline", "breast-cancer", "contact-lenses", "cpu",
"cpu.with.vendor", "credit-g", "diabetes", "glass", "hypothyroid",

rfe_feature_selection_demo(dummy_data, num_features_to_select=2)

Selected Features: Index(['feature2', 'feature4'], dtype='object')
Accuracy with Selected Features: 0.5600

```

## Scheme-specific Selection

**Task 8.1.1** Demonstrate the following quote from the book:

A simple method for accelerating scheme-specific search is to preselect a given number of attributes by ranking them first using a criterion like the information gain and discarding the rest before applying scheme-specific selection.

e.g. ou can combine the statistical correlation with recursive feature elimination shown to you.

## 8.2 Discretizing Numeric Attributes

Unsupervised equal-interval binning is demonstrated early.

**Task 8.2.1** Search and demonstrate the following unsupervised discretization method.

the number of bins is chosen in a data-dependent fashion by setting it to the square root of the number of instances. This method is called *proportional k-interval discretization*.

## Entropy-based

```
# 'information' is the amount of information required to specify the
individual values of yes and no given the split.
# We seek a discretization that makes the subintervals as pure as
possible
# hence, we choose to split at the point where the information value
is smallest.
# in other words, where we don't need to specify a lot to reach yes
and no instances.

import numpy as np
import pandas as pd
from sklearn.preprocessing import KBinsDiscretizer

# Generate some example numeric data
np.random.seed(42)
numeric_data = np.random.rand(100, 1) * 10 # Replace this with your
own numeric data

# Set the number of bins (adjust this based on your dataset)
num_bins = 5

# Create a KBinsDiscretizer with 'entropy' as the criterion
kbd = KBinsDiscretizer(n_bins=num_bins, encode='ordinal',
strategy='uniform', criterion='entropy')

# Fit and transform the numeric data
discretized_data = kbd.fit_transform(numeric_data)

# Convert the result to a DataFrame for better visualization
discretized_df = pd.DataFrame(discretized_data,
columns=['Discretized'])

# Display the original and discretized data side by side
print(pd.DataFrame(np.hstack([numeric_data, discretized_data])),
columns=['Original', 'Discretized'])
```

## 8.3 Projections

### Principal Component Analysis (PCA)

```
import numpy as np
import pandas as pd
import matplotlib.pyplot as plt
from sklearn.datasets import load_iris
from sklearn.decomposition import PCA
from sklearn.preprocessing import StandardScaler
```

```
# Load the Iris dataset
iris = load_iris()
X = iris.data
y = iris.target
feature_names = iris.feature_names

# 4 features
X.shape
(150, 4)

# Standardize the data (important for PCA)
scaler = StandardScaler()
X_std = scaler.fit_transform(X)

# Apply PCA
pca = PCA(n_components=2)
X_pca = pca.fit_transform(X_std)

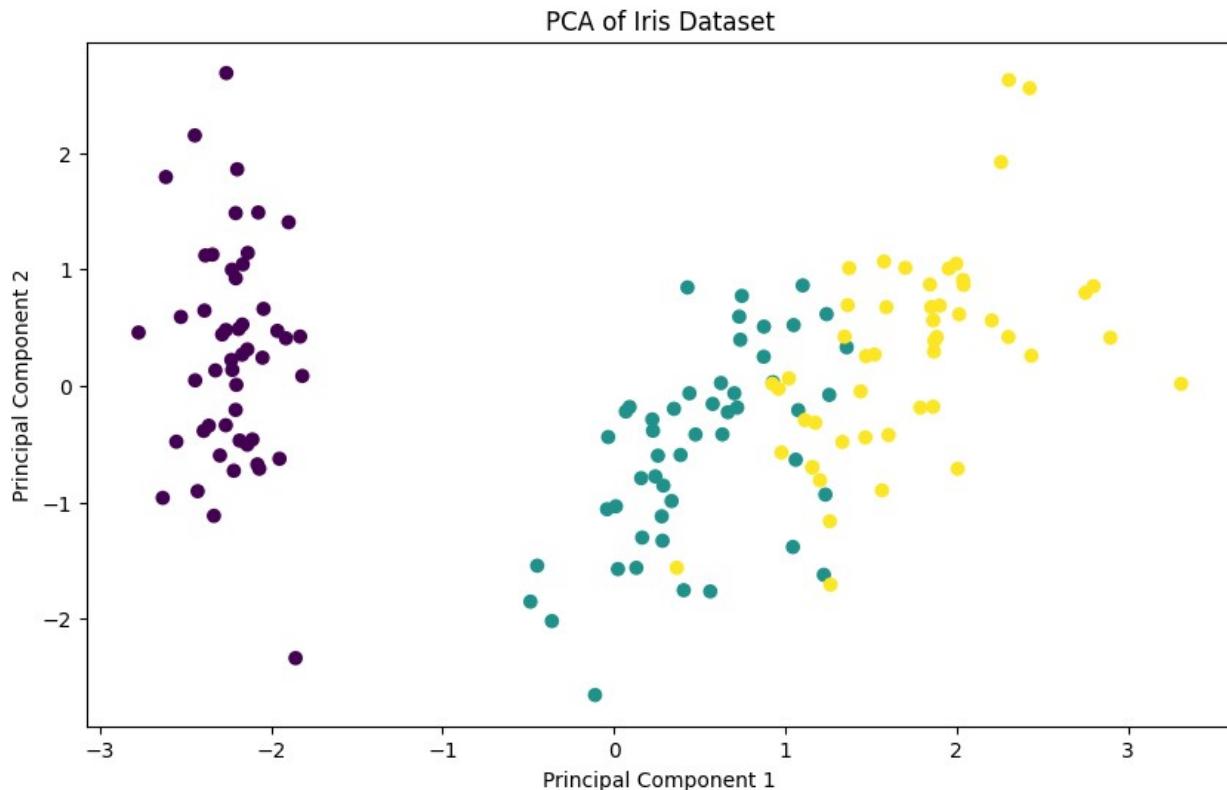

# 2 features in reduced data
X_pca.shape
(150, 2)

# Create a DataFrame for visualization
df_pca = pd.DataFrame(data=X_pca, columns=['Principal Component 1',
'Principal Component 2'])
df_pca['Target'] = y

# Visualize the results
plt.figure(figsize=(10, 6))
plt.xlabel('Principal Component 1')
plt.ylabel('Principal Component 2')
plt.title('PCA of Iris Dataset')

plt.scatter(df_pca['Principal Component 1'], df_pca['Principal Component 2'], c = df_pca['Target'])

plt.show()
```

**Task 8.3.1** Train a machine learning model before and after PCA. Compare evaluation metrics.

## 8.4 Sampling

# Reservoir Sampling

```
# Generating a random sample of an input stream without storing all
# the instances beforehand
# Fill the reservoir
# The next one of stream will be included in the sample with
# probability r/(r+1)

import random

def reservoir_sampling(stream, k):
    """
    Perform reservoir sampling on a data stream.

    Parameters:
    - stream: An iterable representing the data stream.
    - k: The number of elements to sample.

    Returns:
    A list of k sampled elements.
    """

    # Initialize the reservoir with the first k elements
    reservoir = stream[:k]

    for i, item in enumerate(stream[k:], start=k):
        if random.randint(0, i) < k:
            reservoir[i] = item

    return reservoir
```

```

"""
reservoir = []

# Fill the reservoir with the first k elements
for i, element in enumerate(stream):
    if i < k:
        reservoir.append(element)
    else:
        # Randomly replace elements in the reservoir
        j = random.randint(0, i)
        if j < k:
            reservoir[j] = element

return reservoir

# Example usage
data_stream = range(1, 11) # Example data stream from 1 to 100
sample_size = 2

reservoir_sampling(data_stream, sample_size)
[6, 8]

```

## 8.5 Cleansing

**Task 8.5.1** Demonstrate the following.

decision trees induced from training data can often be simplified, without loss of accuracy, by discarding misclassified instances from the training set, relearning, and then repeating until there are no misclassified instances.

You may find code snippets from the previous lab useful.

```

# Media regression

# Robust against outliers

import numpy as np
import statsmodels.api as sm
import matplotlib.pyplot as plt

# Generate some example data
np.random.seed(42)
X = np.random.rand(100, 1) * 10
y = 2 * X + 3 + np.random.normal(0, 1, size=(100, 1))

# Add some outliers to the data

```

```

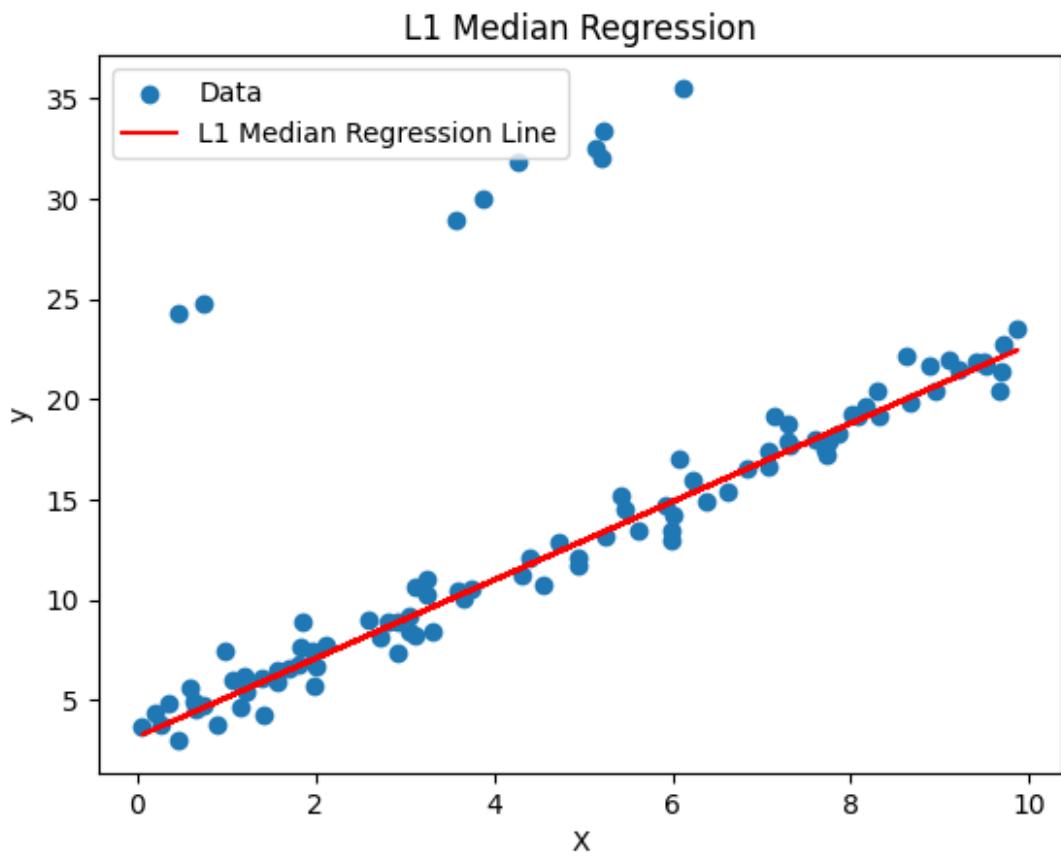

outliers = np.random.randint(0, 100, 10)
y[outliers] += 20 # Introduce outliers

# Perform L1 median regression
X_with_intercept = sm.add_constant(X)
median_model = sm.RLM(y, X_with_intercept,
M=sm.robust.norms.TrimmedMean())
median_results = median_model.fit()

# Get the regression line parameters
intercept, slope = median_results.params

# Visualize the data and the regression line
plt.scatter(X, y, label='Data')
plt.plot(X, intercept + slope * X, color='red', label='L1 Median
Regression Line')
plt.title('L1 Median Regression')
plt.xlabel('X')
plt.ylabel('y')
plt.legend()
plt.show()

```

**Task 8.5.2** Make a regression more robust against outliers by one of the following:

- Train a regression model with absolute-value distance measure instead of the usual squared one.
- Train a regression line and then eliminate the 10% of points that lie furthest from the line.

Compare and evaluate with the standard approach.

## 8.6 Transforming Multiple Classes to Binary Ones

```
# transform multiclass problems into multiple two-class one
# the dataset is decomposed into several two-class problems
# the algorithm is run on each one
# outputs of the resulting classifiers are combined

from sklearn.datasets import load_iris
from sklearn.model_selection import train_test_split
from sklearn.svm import SVC
from sklearn.multiclass import OneVsRestClassifier

# Load the Iris dataset
iris = load_iris()
X, y = iris.data, iris.target

# Split the data into training and testing sets
X_train, X_test, y_train, y_test = train_test_split(X, y,
test_size=0.2, random_state=42)

# Create a Support Vector Machine (SVM) classifier
svm_classifier = SVC(kernel='linear', C=1.0)

# One-vs-Rest strategy
ovr_classifier = OneVsRestClassifier(svm_classifier)

# Train the classifier using the one-vs-rest strategy
ovr_classifier.fit(X_train, y_train)

# Make predictions
y_pred_ovr = ovr_classifier.predict(X_test)

# print
y_pred_ovr

# Observe we have 3 classes
```

```
array([1, 0, 2, 1, 1, 0, 1, 2, 1, 1, 2, 0, 0, 0, 0, 2, 2, 1, 1, 2, 0,  
2,  
     0, 2, 2, 2, 2, 2, 0, 0])
```

**Task 8.6.1** Try *One Vs One* strategy with by substituting line: `ovo_classifier = OneVsOneClassifier(svm_classifier)`. Evaluate and compare results.
